Abstract

One of the most used RCP-Applications to teach people the concept of the 3.x platform is the mail demo generated by the PDE Wizard. In this tutorial we are going to create a similar application using the **Eclipse 4.0 Application Platform**.

This document will not delve into the details about the internals of the Application Platform but will instead focus on showing how one can use it to create an application.

We hope to deliver an in depth book talking about the internals and more advanced information in the 4.1 timeframe.

Setup the IDE

Probably the most natural way to develop an Eclipse 4.0 application is to download the Eclipse 4.0 SDK which uses the **Eclipse 4.0 Application Platform** to provide you a Java and OSGi-Tooling-IDE.

We should mention at this point that you are NOT forced to use the Eclipse 4.0 SDK to write Eclipse 4.0 applications and all the introduced tooling is available to you as well in the Helios Release through the e4 Update-Site of the Eclipse-IDE.

Though we appreciate if you use Eclipse 4.0 SDK as your IDE we'd like to mention that it is not targeted yet for daily work but marked as an "Early Adopter Release" giving plugin developers the possibility to test if their 3.x bundles run in a 4.0 environment.

Download & Install Eclipse 4.0 SDK

You should be able to download Eclipse 4.0 SDK from <http://eclipse.org/eclipse4/> . Featurewise what you get with this download is comparable to Eclipse Classic 3.6 that includes JDT, PDE, CVS,

After having downloaded the Eclipse version for your platform you'll have to unzip it and launch the platform executable and you should see an 4.0 SDK similar to this one:

Figure 1: 4.0 SDK

Install Eclipse 4.0 (Model)Tooling

The Eclipse 4.0 tooling provides a specialized editor designed with the Eclipse 4.0 application model in mind and simplifies working with it.

If you don't want to use the tooling you can also use standard EMF-Tools to work with the application model but most people will probably prefer the specialized editor we are using through out this tutorial.

Because the Eclipse 4.0 Tooling has not yet graduated into the 4.0 SDK you need to install it using Help > Install New Software

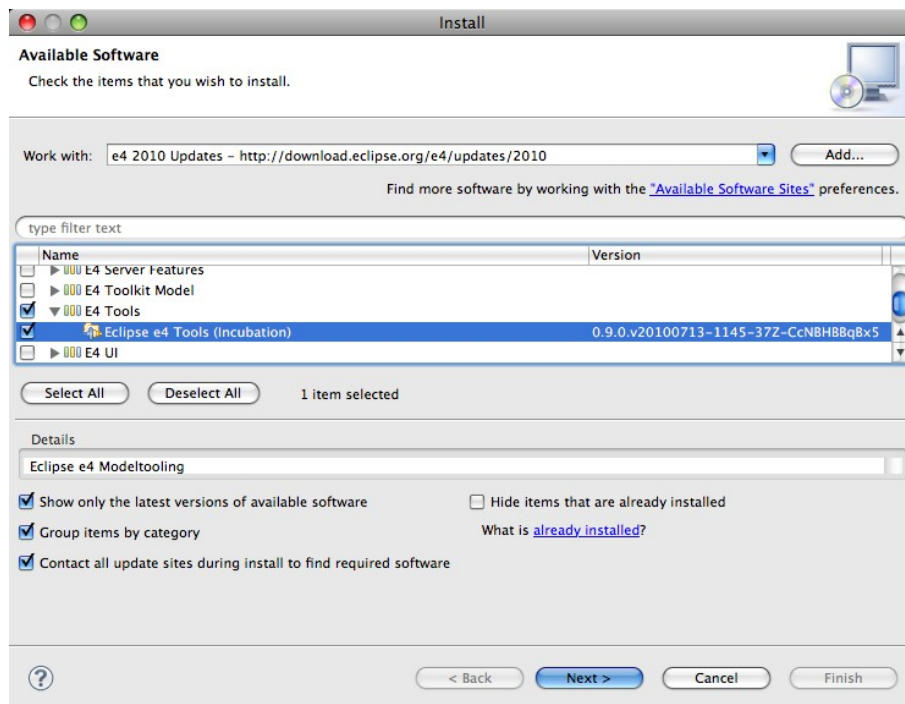

Figure 2: Install Eclipse 4.0 Tooling

DO NOT INSTALL ANY XWT-TOOLING STUFF – AT LEAST ON MY OS-X SYSTEM THE VISUAL WORKBENCH-MODELEditor IS BROKEN

Setup project

There is a wizard for creating a complete Eclipse 4.0 Application project but we will not be using that wizard. Instead, we will setup the project by hand so that we understand exactly what is going on in the back.

Create an OSGi-Project

We are using File > New > Project ... and select Plug-in Development > Plug-in Project and enter the following data into the wizard pages:

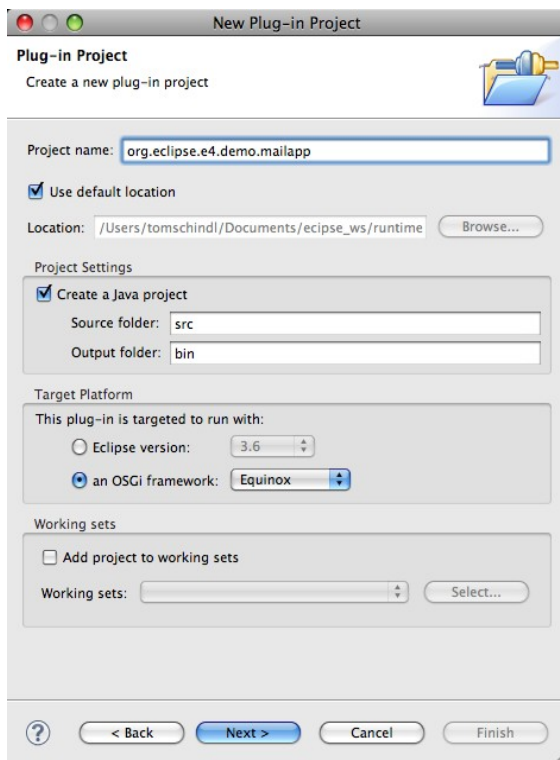

Figure 3: New OSGi-Project 1

Figure 4: New OSGi-Project 2

Add a product definition

In order to create something we can launch and export we are creating an Equinox application and product definition by using the extension points provided by "org.eclipse.equinox.app".

To write an Eclipse 4.0 Application, we don't have to define our own application but reuse an application already defined by the Eclipse 4.0 Application Platform named "org.eclipse.e4.ui.workbench.swt.E4Application".

Let's do things step by step:

a) Open the MANIFEST.MF

Add a dependency on "org.eclipse.equinox.app"

b) Create a plugin.xml

Add a product definition like this

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.4"?>
<extension
    id="product"
    point="org.eclipse.core.runtime.products">
  <product
    application="org.eclipse.e4.ui.workbench.swt.E4Application"
    name="Mail App">
  </product>
</extension>
```

`</extension>`

As an alternative you can use the "Extension"-Tab in the MANIFEST.MF-Editor – in case it is not shown select the Extension-Link on the "Overview"-tab.

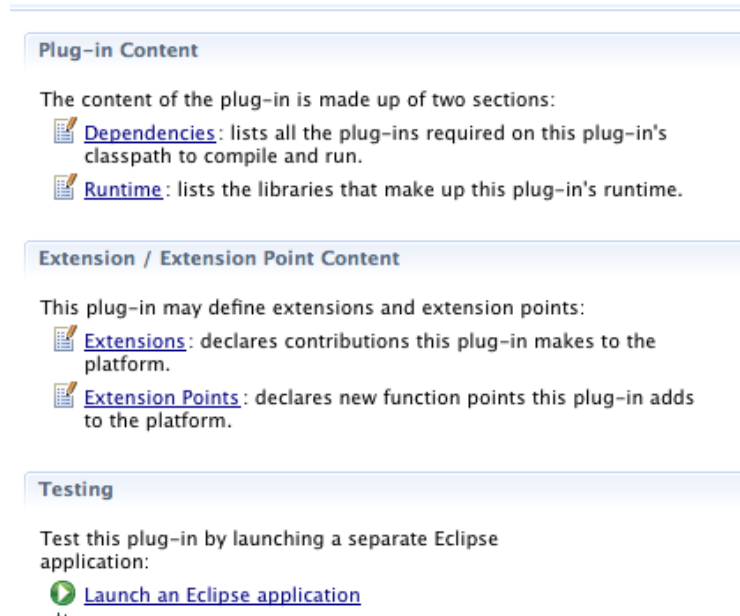

Figure 5: Extension

We are still missing two things before we can launch our application:

- An Eclipse 4.0 Application which uses the predefined E4Application has to have a minimal workbench model (we'll learn about this in the upcoming sections)
- A .product to define a launchable and exportable application.

Add a minimal Eclipse 4.0-ApplicationModel

In contrast to 3.x applications where you used a mixture of Java and Extension Points to setup up an application the Eclipse 4.0 Application Platform follows another route. The complete application is defined and made up from one single model.

You'll learn in later sections of the tutorial how this application model can be made up dynamically but for getting something up and running we'll create a minimal application model using "File > New > Other" and select "e4 > Model > New Application Model".

Fill in the following information:

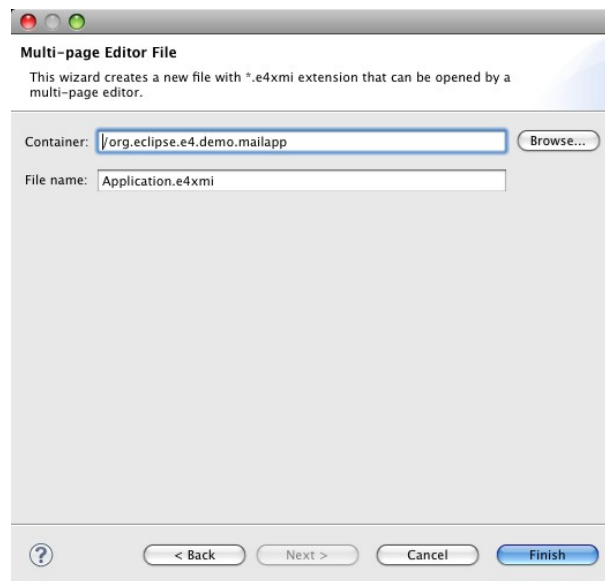

Figure 6: New Application Model

Technically this would be enough to launch an application, but a UI-Application without at least one window is quite senseless.

After having created the Application.e4xmi, the “e4 Workbench Model”-Editor should have opened itself automatically.

Select the “Windows” entry on the left, select “TrimmedWindow” on the right and press the button next to the drop down. The result should be an editor looking like this:

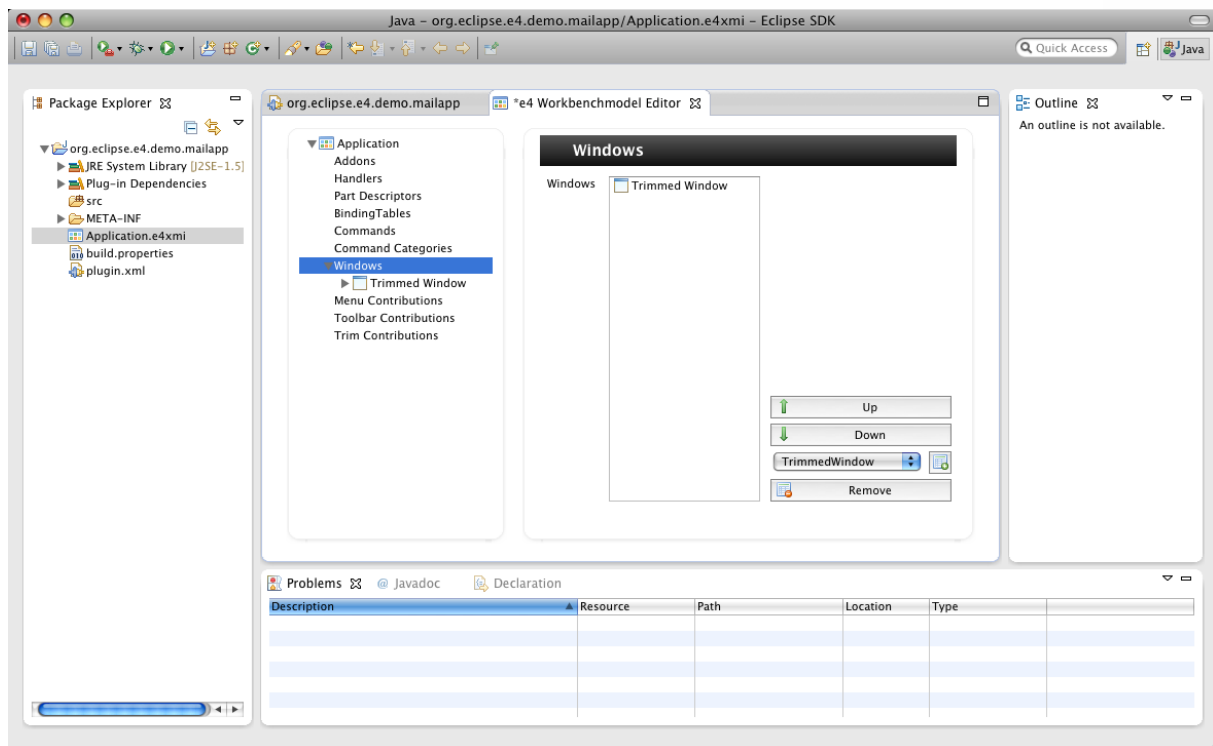

Figure 7: Add window to model

Afterwards select the "Trimmed Window" entry in the tree and set the height and width values to 640 and 480 and the Label-Property to "MailDemo 4.0". Let's take a look at what is written to Application.e4xmi:

```
<?xml version="1.0" encoding="ASCII"?>
<application:Application
  xmi:version="2.0"
  xmlns:xmi="http://www.omg.org/XMI"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:application="http://www.eclipse.org/ui/2010/UIModel/application"
  xmlns:basic="http://www.eclipse.org/ui/2010/UIModel/application/ui/basic"
  xmi:id="_K-zoJS1Ed-3RJVy90YaEA"
  elementId="org.eclipse.e4.demo.mailapp.application">
  <children
    xsi:type="basic:TrimmedWindow"
    xmi:id="_mWWEUJS2Ed-3RJVy90YaEA"
    label="MailDemo 4.0"
    width="640"
    height="480"/>
  </children>
</application:Application>
```

You normally don't have to edit this file by hand because Eclipse 4.0 provides tooling and I'd also like to point out that XMI is only one possible serialization format of the EMF Model we just created – yes you've just created your first instance of an EMF Model.

The default system expects to have a model loaded from such an XMI-File but the framework allows you to replace this by your own model

loading/construction strategy if you are not comfortable with the default – all the framework cares about internally is to get an in memory EMF Model of the application whether loaded from XMI, constructed on the fly, loaded over the wire, ... is something totally up to you.

One of the important things you notice in the file are the `xmi:id` attributes who have a very cryptic value that is needed by the default implementation used to restore the application state when started.

Create a MailDemo-4.0.product

A product file allows us to define a product we'll export later on to provision on our clients' desktops. You should familiarize yourself with the process of creating such a ".product" but here's a step by step instruction because we need to add some extra stuff PDE is not able resolve on its own.

1. New > File > Other ...
2. Plug-in Development > Product Configuration
3. In dialog enter:
 - Filename: MailDemo-4.0
 - Use an existing product: `org.eclipse.e4.demo.mailapp.product`
4. Add the following additional bundles
 - `org.eclipse.equinox.ds`: This adds declarative OSGi services who use the extender pattern and so none of the framework has a dependency on it
 - `org.eclipse.equinox.event`: This provides e4 the event system it uses internally for communication and can be used by you as well
 - `org.eclipse.e4.ui.workbench.renderers.swt`: e4 comes with a very flexible rendering system which allows people to completely replace the rendering. We are using the default one provided by e4 team.
5. Press „Add Required Plug-ins“

Before we can launch, we need to add some more information to our product-extension point to make it look like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.4"?>
<plugin>
  <extension
    id="product"
    point="org.eclipse.core.runtime.products">
    <product
      application="org.eclipse.e4.ui.workbench.swt.E4Application"
      name="Mail App">
    </product>
  </extension>
</plugin>
```

```
        name="appName"
        value="Mail App">
    </property>
    <property
        name="applicationXMI"
        value="org.eclipse.e4.demo.mailapp/Application.e4xmi">
    </property>
    </product>
</extension>

</plugin>
```

The important information we need to provide to the E4Application is, what initial model it should use to make up the application.

Now we are ready to launch our minimal Eclipse 4.0 application the first time and it will show us something like this:

Figure 8: First Application

Want the source code? Look at "Source Zip for Chapter 2" on page 58.

Create the MailServices

To let our application really do meaningful stuff and present you all the cool new features the Eclipse 4.0 Application Platform provides you when writing OSGi based UI applications, we are going to add some OSGi service stuff.

The Eclipse 4.0 Application Platform itself is designed from day one with OSGi in mind and so in order to follow good OSGi practices we create 2 new OSGi-projects:

- org.eclipse.e4.demo.mailapp.mailservice
- org.eclipse.e4.demo.mailapp.mailservice.mock

We are not going into details here how this is implemented but you should

simply download the premade bundles and import them in your workspace.

The premade bundles are available from "Premade Service-Bundle" on page 58.

The important APIs for now are:

- `IMailSessionFactory#openSession()`: Allows you to open a mail session
- `IMailSession#getAccounts()`: used to retrieve mail accounts
- `IMailSession#getMails()`: used to fetch mails from a folder

If you are not familiar with Declarative OSGi Services, there's a vast number of tutorials and books describing them in great detail.

After having imported the bundles your workspace should look like this:

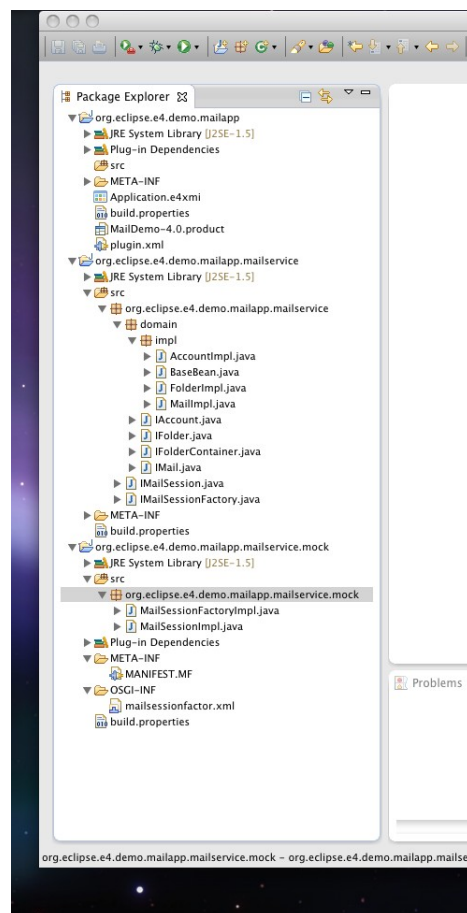

Figure 9: Workspace after ServiceBundles import

To finish this task we need to add the 2 new bundles to our ".product" file and recreate our launch configuration so that those new bundles are picked up.

Create the UI

Next thing we need to do is to write our UI-Code. In 3.x we would have derived our UI-Parts from ViewPart or EditorPart but this is not needed anymore when using the Eclipse 4.0 Application Platform where everything is a POJO.

Before we can start writing our UI code, we need to add the following dependencies to our MANIFEST.MF in "org.eclipse.e4.demo.mailapp":

- org.eclipse.swt
- org.eclipse.jface
- org.eclipse.jface.databinding
- org.eclipse.core.databinding
- org.eclipse.core.databinding.observable
- org.eclipse.core.databinding.property
- org.eclipse.core.databinding.beans (this one you also has to added to ".product" file – don't forget to update your launch-config!)
- org.eclipse.e4.demo.mailapp.mailservice

Implement the AccountView UI

Next we create a new Java-Class named org.eclipse.e4.demo.mailapp.AccountView and add the following lines of Java-Code into it.

```
public class AccountView {
    private IMailSessionFactory mailSessionFactory;
    private IMailSession mailSession;
    private TreeViewer viewer;
    private String username = "john";
    private String password = "doe";
    private String host = "tomsondev.bestsolution.com";

    public AccountView(Composite parent, IMailSessionFactory mailSessionFactory) {
        this.mailSessionFactory = mailSessionFactory;
        viewer = new TreeViewer(parent, SWT.FULL_SELECTION);
        viewer.setLabelProvider(new ColumnLabelProvider() {
            @Override
            public String getText(Object element) {
                if( element instanceof IAccount ) {
                    return ((IAccount) element).getName();
                } else if( element instanceof IFolder ) {
                    return ((IFolder)element).getName();
                }
                return super.getText(element);
            }
        });
    }
}
```

```

    }
    });

    IObservableFactory factory = new IObservableFactory() {
        private IListProperty prop = BeanProperties.list("folders");

        public IObservable createObservable(Object target) {
            if( target instanceof IObservableList ) {
                return (IObservable) target;
            } else if( target instanceof IFolderContainer ) {
                return prop.observe(target);
            }
            return null;
        }
    };

    TreeStructureAdvisor advisor = new TreeStructureAdvisor() {};

    viewer.setContentProvider(new ObservableListTreeContentProvider(factory, advisor));
}

public void setUsername(String username) {
    this.username = username;
}

public void setPassword(String password) {
    this.password = password;
}

public void setHost(String host) {
    this.host = host;
}

public void init() {
    if( username != null && password != null && host != null ) {
        mailSession = mailSessionFactory.openSession(host, username, password);
        viewer.setInput(mailSession.getAccounts());
    }
}
}
}

```

How can we test this UI? We could add it directly to our Eclipse 4.0 application but when looking closer, we see that there's no need to bring up the complete framework to see what our fragment is doing.

There's not even a dependency on an OSGi environment so the class above should be runnable as a standard Java-Application.

Create a TestProject

We create a Test project we can use to launch our UI codeparts who have now no real dependency on the Application-Framework nor OSGi itself.

Although we are writing a standard Java application let's create a PDE-enabled project named "org.eclipse.e4.demo.mailapp.test" so that we don't have to manage the classpath ourselves.

Add the following dependencies to the MANIFEST.MF:

- org.eclipse.swt
- org.eclipse.jface.databinding
- org.eclipse.core.databinding
- org.eclipse.e4.demo.mailapp
- org.eclipse.e4.demo.mailapp.mailservice
- org.eclipse.e4.demo.mailapp.mailservice.mock
- org.eclipse.core.runtime

Open the MANIFEST.MF in "org.eclipse.e4.demo.mailapp" and export the "org.eclipse.e4.demo.mailapp"-package so that it is visible in our test-bundle.

Add a TestAccountView-Class:

```
public class TestAccountView {
    public static void main(String[] args) {
        final Display d = new Display();
        Realm.runWithDefault(SWTObservables.getRealm(d), new Runnable() {

            public void run() {
                Shell shell = new Shell(d);
                shell.setLayout(new FillLayout());
                AccountView view = new AccountView(shell, new MailSessionFactoryImpl());
                view.setUsername("john");
                view.setPassword("doe");
                view.setHost("tomsondev.bestsolution.at");
                view.init();

                shell.open();

                while( !shell.isDisposed() ) {
                    if( ! d.readAndDispatch() ) {
                        d.sleep();
                    }
                }
            }
        });

        d.dispose();
    }
}
```

Now launch it as a standard Java-Application and you should see something like this:

Figure 10: Test Account UI

Create the FolderView UI

This view displays all mails of a folder in a SWT table. Here's the code and the class to test it.

```
public class FolderView {
    private TableViewer viewer;

    public FolderView(Composite parent) {
        this.viewer = new TableViewer(parent);
        this.viewer.setContentProvider(new ArrayContentProvider());
        this.viewer.getTable().setHeaderVisible(true);
        this.viewer.getTable().setLinesVisible(true);

        TableViewerColumn column = new TableViewerColumn(viewer, SWT.NONE);
        column.getColumn().setText("Subject");
        column.getColumn().setWidth(250);
        column.setLabelProvider(new ColumnLabelProvider() {
            @Override
            public String getText(Object element) {
                return ((IMail)element).getSubject();
            }
        });

        column = new TableViewerColumn(viewer, SWT.NONE);
        column.getColumn().setText("From");
        column.getColumn().setWidth(200);
        column.setLabelProvider(new ColumnLabelProvider() {
            @Override
            public String getText(Object element) {
                return ((IMail)element).getFrom();
            }
        });

        column = new TableViewerColumn(viewer, SWT.NONE);
        column.getColumn().setText("Date");
        column.getColumn().setWidth(150);
        column.setLabelProvider(new ColumnLabelProvider() {
            private DateFormat format = SimpleDateFormat.getDateTimeInstance();

            @Override
            public String getText(Object element) {
```

```

        Date date = ((IMail)element).getDate();
        if( date != null ) {
            return format.format(date);
        }
        return "-";
    }
}
});
}

public void setFolder(IFolder folder) {
    viewer.setInput(folder.getSession().getMails(folder, 0, folder.getMailCount()));
}
}
}

```

And the class to test it:

```

public class TestFolderView {
    public static void main(String[] args) {
        final Display d = new Display();
        Realm.runWithDefault(SWTObservables.getRealm(d), new Runnable() {

            public void run() {
                Shell shell = new Shell(d);
                shell.setLayout(new FillLayout());
                FolderView view = new FolderView(shell);
                view.setFolder(((IAccount)new MailSessionFactoryImpl().openSession(
                    "", "john", "doe").getAccounts().get(0)).getFolders().get(0)
                );

                shell.open();
                while( !shell.isDisposed() ) {
                    if( ! d.readAndDispatch() ) {
                        d.sleep();
                    }
                }
            }
        });
        d.dispose();
    }
}

```

The UI you should see when running the Java Application looks like this:

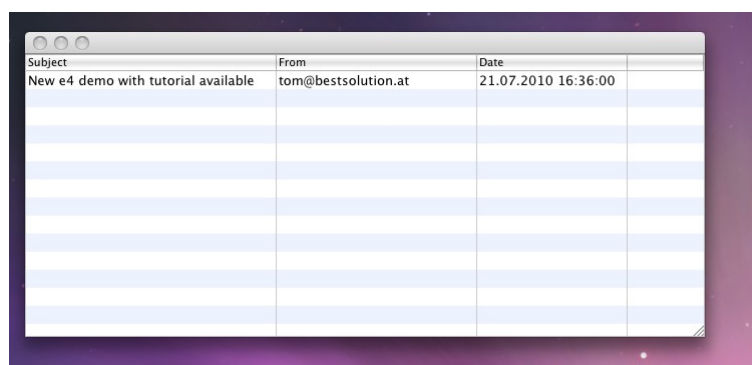

Figure 11: Test FolderView

Create the Mail UI

This UI displays a mail to the user. The Java code for the View looks like this:

```
public class MailView {
    private DataBindingContext dbc;
    private WritableValue mail = new WritableValue();
    private ObservablesManager manager;

    public MailView(final Composite composite) {
        dbc = new DataBindingContext();
        manager = new ObservablesManager();
        manager.runAndCollect(new Runnable() {
            public void run() {
                initUI(composite);
            }
        });
    }

    public void setMail(IMail mail) {
        if( mail != null ) {
            this.mail.setValue(mail);
        }
    }

    private void initUI(Composite composite) {
        Composite parent = new Composite(composite, SWT.NONE);
        GridLayout gd = new GridLayout();
        gd.horizontalSpacing=0;
        gd.verticalSpacing=0;
        parent.setLayout(gd);

        Composite header = new Composite(parent,SWT.NONE);
        header.setLayout(new GridLayout(2,false));
        header.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));

        Label l = new Label(header, SWT.NONE);
        l.setText("From");

        l = new Label(header, SWT.NONE);
        l.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
        dbc.bindValue(WidgetProperties.text().observe(l),
            BeanProperties.value("from").observeDetail(mail));

        l = new Label(header,SWT.NONE);
        l.setText("Subject");

        l = new Label(header, SWT.NONE);
        l.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
        dbc.bindValue(WidgetProperties.text().observe(l),
            BeanProperties.value("subject").observeDetail(mail));

        l = new Label(header,SWT.NONE);
        l.setText("To");

        l = new Label(header, SWT.NONE);
        l.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
        dbc.bindValue(WidgetProperties.text().observe(l),
            BeanProperties.value("to").observeDetail(mail));

        l = new Label(parent, SWT.SEPARATOR|SWT.HORIZONTAL);
        l.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
    }
}
```

```

Text t = new Text(parent, SWT.BORDER|SWT.V_SCROLL|SWT.H_SCROLL|SWT.WRAP);
t.setLayoutData(new GridData(GridData.FILL_BOTH));
t.setEditable(false);
dbc.bindValue(WidgetProperties.text().observe(t),
    BeanProperties.value("body").observeDetail(mail));
}

public void dispose() {
    manager.dispose();
}
}

```

And the class to test it:

```

public class TestMailView {
    public static void main(String[] args) {
        final Display d = new Display();
        Realm.runWithDefault(SWTObservables.getRealm(d), new Runnable() {

            public void run() {
                Shell shell = new Shell(d);
                shell.setLayout(new FillLayout());
                MailView view = new MailView(shell);
                IFolder folder = ((IAccount)new MailSessionFactoryImpl().openSession(
                    "", "john", "doe").getAccounts().get(0)).getFolders().get(0);

                view.setMail(folder.getSession().getMails(folder, 0, 1).get(0));
                shell.open();

                while( !shell.isDisposed() ) {
                    if( ! d.readAndDispatch() ) {
                        d.sleep();
                    }
                }
            }
        });
        d.dispose();
    }
}

```

Running the test-Program should create a UI like this:

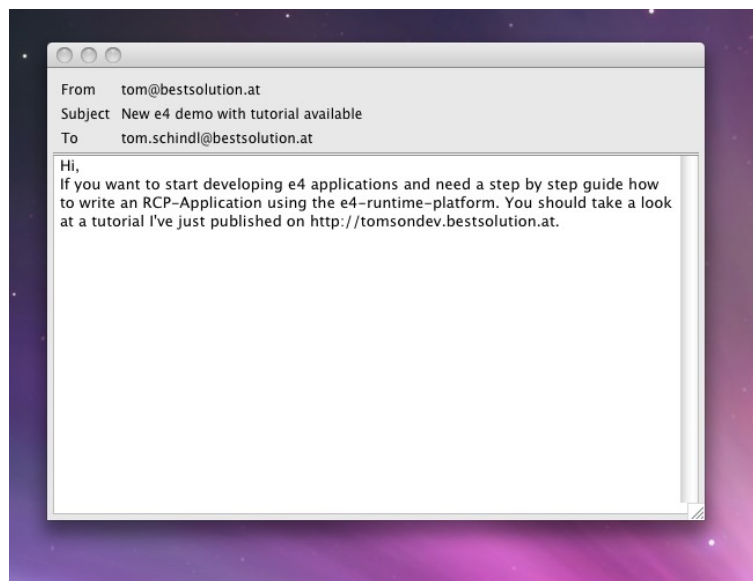

Figure 12: Test MailView

We now have created all the UI parts of our application without the need to have any knowledge about the Eclipse 4.0 Application Platform. All we had to know was SWT/JFace and how to program in Java.

Want the source code? Look at "Source Zip for Chapter 4" on page 58.

Assemble an Eclipse 4.0-Application

DI and the POJO Application Programming Model

We now have 3 UI classes that on their own don't make much sense but together they are able to build a complete MailReader application.

Before we start with the process of integrating our POJOs in the application model I think it makes sense to explain what we are going to do in the next few sections of this tutorial.

I assume most of you have already heard at least once about Dependency Injection (DI). Those of you who have ever worked with Spring or Guice are familiar with the concepts. For others who never have - don't be afraid, it's not really not rocket science.

Let's take a look at a typical 3.x sample code, dealing with the change of the current selection in the workbench.

```
public class View extends ViewPart {  
  
    public void createPartControl(Composite parent) {  
  
        getSite().getSelectionProvider().addSelectionChangedListener(new ISelectionChangedListener() {  
            public void selectionChanged(SelectionChangedEvent event) {  
                if( event.getSelection() instanceof IStructuredSelection) {
```

```
Object o = ((IStructuredSelection)event.getSelection()).getFirstElement();

    if( o instanceof IFolder ) {
        updateFolder((IFolder) o);
    }
}

});
}

void updateFolder(IFolder folder) {
    // Do something when selection changes
}
}
```

And here's what you write when using the Eclipse 4.0 Application Platform:

```
public class View {
    @Inject
    void updateFolder(@Named(IServiceConstants.ACTIVE_SELECTION) IFolder folder) {
        // Do something when selection changes
    }
}
```

The first thing you notice is that the code is much more concise and you don't have to write tons of glue code but what is more interesting is that you are flipping sides.

Instead of being the active part, you play the inactive one who gets informed automatically if something changes you are interested in.

This makes your code much more reusable because you are not depending on external stuff like the ISelectionService being available.

I'm not going into great detail here now because DI is a very wide area. The important thing for us is that we'll have to add annotations like **@Inject** at various places in our code (constructors, fields, methods) to get information we need to make up the UI.

There's no other way to get access to information because the Eclipse 4.0 Application Platform doesn't provide statics or singletons like the 3.x platform did!

Before we start adding the annotations to our code we have to add some more bundles to our MANIFEST.MF:

- javax.inject
- javax.annotation
- org.eclipse.e4.core.di
- org.eclipse.e4.ui.services

Those provide the annotations we are going to add to our code and some constants.

Modify the AccountView like this:

```
public class AccountView {
    @Inject
    public AccountView(Composite parent, IMailSessionFactory mailSessionFactory) {
        // Unmodified
    }

    @PostConstruct
    public void init() {
        // Unmodified
    }
}
```

Modify the FolderView like this:

```
public class FolderView {
    @Inject
    public FolderView(Composite parent) {
        // Unmodified
    }

    @Inject
    public void setFolder(@Named(IServiceConstants.ACTIVE_SELECTION) @Optional IFolder folder) {
        // Unmodified
    }
}
```

and the MailView like this:

```
public class MailView {
    @Inject
    public MailView(final Composite composite) {
        // Unmodified
    }

    @Inject
    public void setMail(@Named(IServiceConstants.ACTIVE_SELECTION) @Optional IMail mail) {
        // Unmodified
    }

    @PreDestroy
    public void dispose() {
        // Unmodified
    }
}
```

Let's try to understand the code parts above a bit better. The first thing you need to know is that the instance creation and destruction is handled by the Eclipse-4.0 DI-container.

When some code requests an instance of e.g. AccountView the DI-Framework searches through constructors annotated with **@Inject** and tries to satisfy the arguments of the constructor. The informations required to call the constructor

are looked up in the so called `IEclipseContext` that you can think of as a Map of type `Map<String, Object>`.

For the `AccountView`-constructor from above it searches for 2 keys:

- `org.eclipse.swt.widget.Composite`
- `org.eclipse.e4.demo.mailapp.mailservice.IMailSessionFactory`

and passes the value found to the constructor.

After having created an instance of the class it searches for fields and methods annotated with **@Inject** and looks up their value.

In contrast to ordinary constructor injection, it remembers the injected keys and whenever the value connected to the key changes it reinjects the changed value.

A special thing in this context is the usage of **@Named** that allows one to define the key to be used when looking up the value (by default the fully qualified class name is used).

The **@Optional** annotation means that if no value is found or the value stored under the key can not be converted to the required type, the system should pass in `null` instead.

The other 2 annotations you see are controlling the life cycle of an object. Methods annotated with **@PostConstruct** are called after the object is created and all injections are done (field and method).

The **@PreDestroy** is the opposite. It is called before the object is destroyed by the DI-container and provides the possibility to clean up resources allocated by the POJO.

Wiring the POJOs into the Application Model

As noted above the Eclipse 4.0 Application Platform at its heart is a DI-container that controls the entire application and connects bits and pieces to make up a complete application from those small POJOs.

To connect all this information, it uses the application model we've already used to define the initial layout of our application. Our POJOs from above are now going to get part of the application model and because of the DI-annotations we added, the application framework knows how to create instances whenever it needs one.

a) Open the `Application.e4xmi` and create a structure like this:

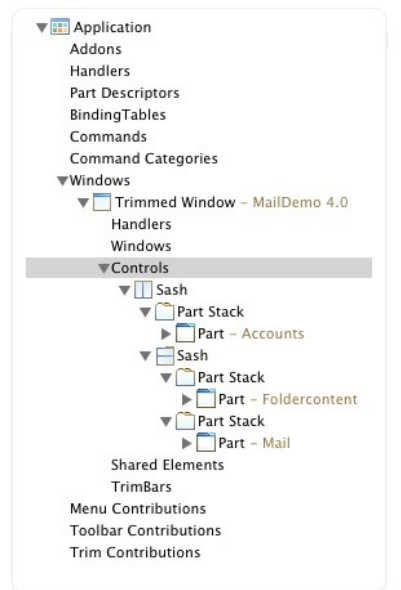

Figure 13: UI Model for Mail 4.0

b) Select the 1st Part in the tree and press the "Find..."-button on the Class URI attribute and search for our AccountView-POJO.

Abbildung 14: Connect POJO with UI

c) Select the 2nd Part in the tree, press the "Find..."-button and select the "FolderView"

d) Select the 3rd in the tree, press the „Find..."-button and select the "MailView"

What we've done in steps b) to d) is to wire our UI model with our POJOs and now at the moment the application has to render a part which is connected to such a POJO it creates an instance through the DI-Container and hands over control for this area to the POJO.

When launching our application we should see something like this:

Figure 15: Running MailDemo Application

But there's still one thing missing. When selecting an entry in the account area the list of mails is not updated. The problem you are seeing here is that the AccountView has to inform others about the changed selection.

This information can be passed around by a special service named ESelectionService. To get access to this service, you need to add "org.eclipse.e4.ui.workbench" to your MANIFEST.MF and modify the UI code like this:

AccountView:

```
public class AccountView {
    @Inject
    @Optional
    private ESelectionService selectionService;

    @Inject
    public AccountView(Composite parent, IMailSessionFactory mailSessionFactory) {
        // Unmodified
        viewer.addSelectionChangedListener(new ISelectionChangedListener() {
            public void selectionChanged(SelectionChangedEvent event) {
                if( selectionService != null ) {
                    selectionService.setSelection(
                        ((IStructuredSelection)event.getSelection()).getFirstElement()
                    );
                }
            }
        });
    }
}
```

```

        });
    }
}

@PostConstruct
public void init() {
    // Unmodified
}
}

```

FolderView:

```

public class FolderView {

    @Inject
    @Optional
    private ESelectionService selectionService;

    @Inject
    public FolderView(Composite parent) {
        // Unmodified
        viewer.addSelectionChangedListener(new ISelectionChangedListener() {
            public void selectionChanged(SelectionChangedEvent event) {
                if( selectionService != null ) {
                    selectionService.setSelection(
                        ((IStructuredSelection)event.getSelection()).getFirstElement()
                    );
                }
            }
        });
    }

    @Inject
    public void setFolder(@Named(IServiceConstants.ACTIVE_SELECTION) @Optional IFolder folder) {
        // Unmodified
    }
}

```

The application should now behave as expected and look like this.

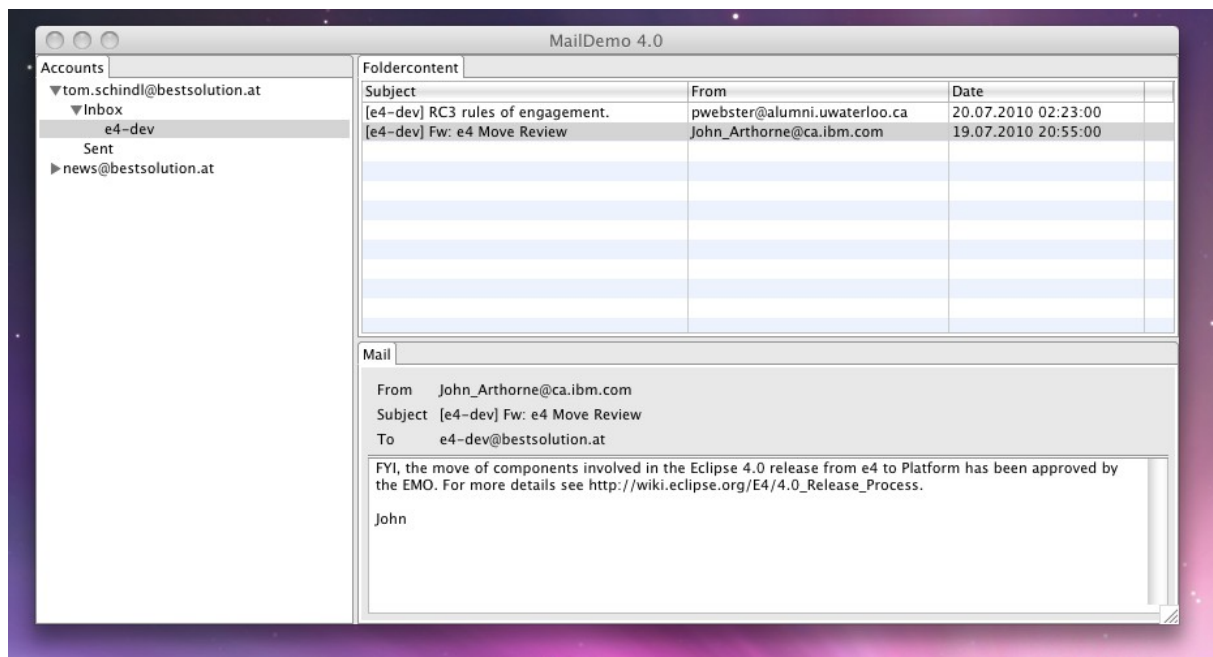

Figure 16: Running MailDemo Application after chapter 5

Want the source code? Look at "Source Zip for Chapter 5" on page 58.

Improve the Application L&F

Now that we have a running application, we can work on a more modern look and feel.

To customize the L&F of applications, the Eclipse 4.0 Application Platform provides us with a CSS-like declarative syntax.

In order to tell the framework what CSS stylesheet it has to apply to the application we need to:

- Create a directory called "css"
- Add a file called "default.css"
- Modify the plugin.xml like this

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.4"?>
<plugin>
  <extension
    id="product"
    point="org.eclipse.core.runtime.products">
    <product
      application="org.eclipse.e4.ui.workbench.swt.E4Application"
      name="Mail App">
      <property
        name="appName"
```

```

        value="Mail App">
    </property>
    <property
        name="applicationXMI"
        value="org.eclipse.e4.demo.mailapp/Application.e4xmi">
    </property>
    <property
        name="applicationCSS"
        value="platform:/plugin/org.eclipse.e4.demo.mailapp/css/default.css">
    </property>
</product>
</extension>

</plugin>

```

The applicationCSS-property informs the system about the fact that there's a CSS stylesheet which has to be applied to the whole RCP application.

Defining the above property is all you need to do to tell your application to consume a CSS stylesheet.

Here's the initial CSS information we are adding:

```

.MTrimmedWindow {
    background-color: #E8E8E8;
    margin-top: 10px;
    margin-bottom: 2px;
    margin-left: 5px;
    margin-right: 5px;
}

.MPartStack {
    tab-renderer:
url('platform:/plugin/org.eclipse.e4.ui.workbench.renderers.swt/org.eclipse.e4.ui.workbench.renderers.swt.CTabRendering');
    unselected-tabs-color: #FFFFFF #FFFFFF #FFFFFF 100% 100%;
    outer-keyline-color: #FFFFFF;
    inner-keyline-color: #FFFFFF;
    font-size: 12;
}

```

What you see above is the definition of 2 CSS classes MTrimmedWindow and MPartStack. The name of those classes are the ones of the Application-Model elements we used prefixed with an "M".

I think I don't have to explain in great detail the attributes defined in MTrimmedWindow. Maybe the only remarkable thing is that the margin information is not interpreted by the SWT-Widget but needs programmatic intervention by the programmer updating the layout.

The information on MPartStack is more interesting because they differ from what we know from the Web.

The most interesting one is the tab-renderer attribute which is pointing to a Java class one can set since 3.6 on a CTabFolder to influence how it is drawn.

To find out what the others are doing I'd suggest you play around to see what their effect is.

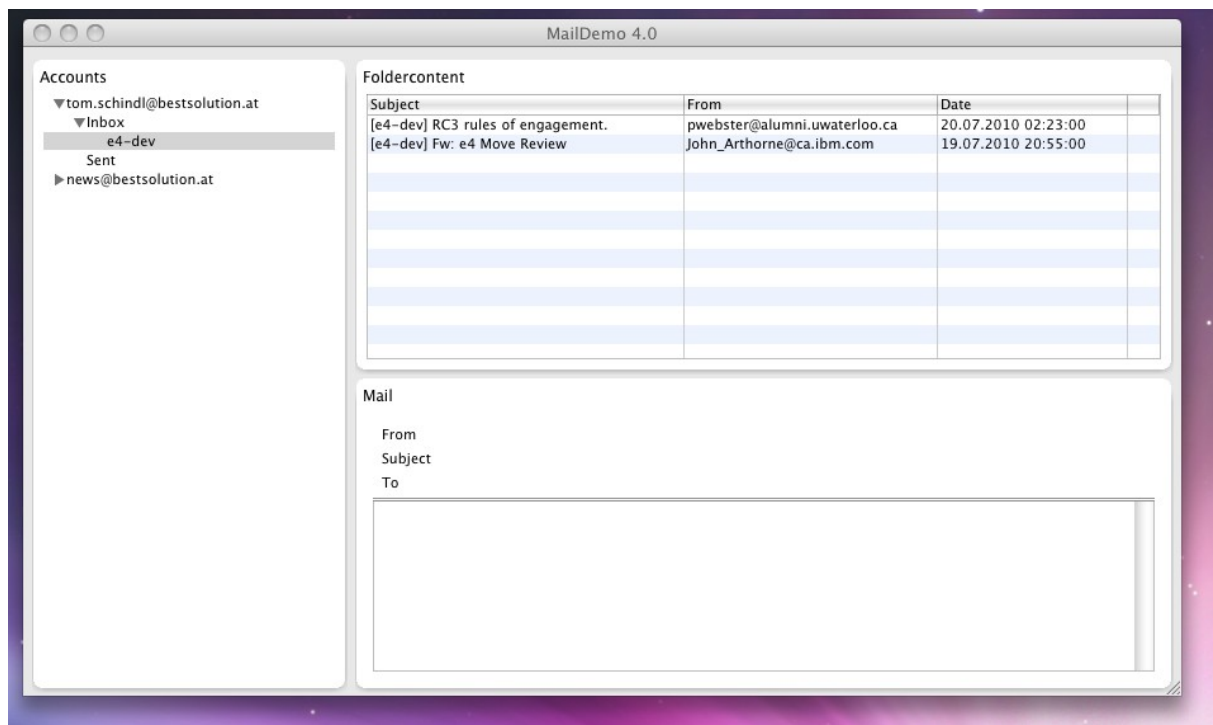

Figure 17: MailDemo with CSS

The first set of style information have been applied to widget owned by the Eclipse 4.0 Application Platform but we'd also like to apply css information on the widgets created by the Part-POJOs.

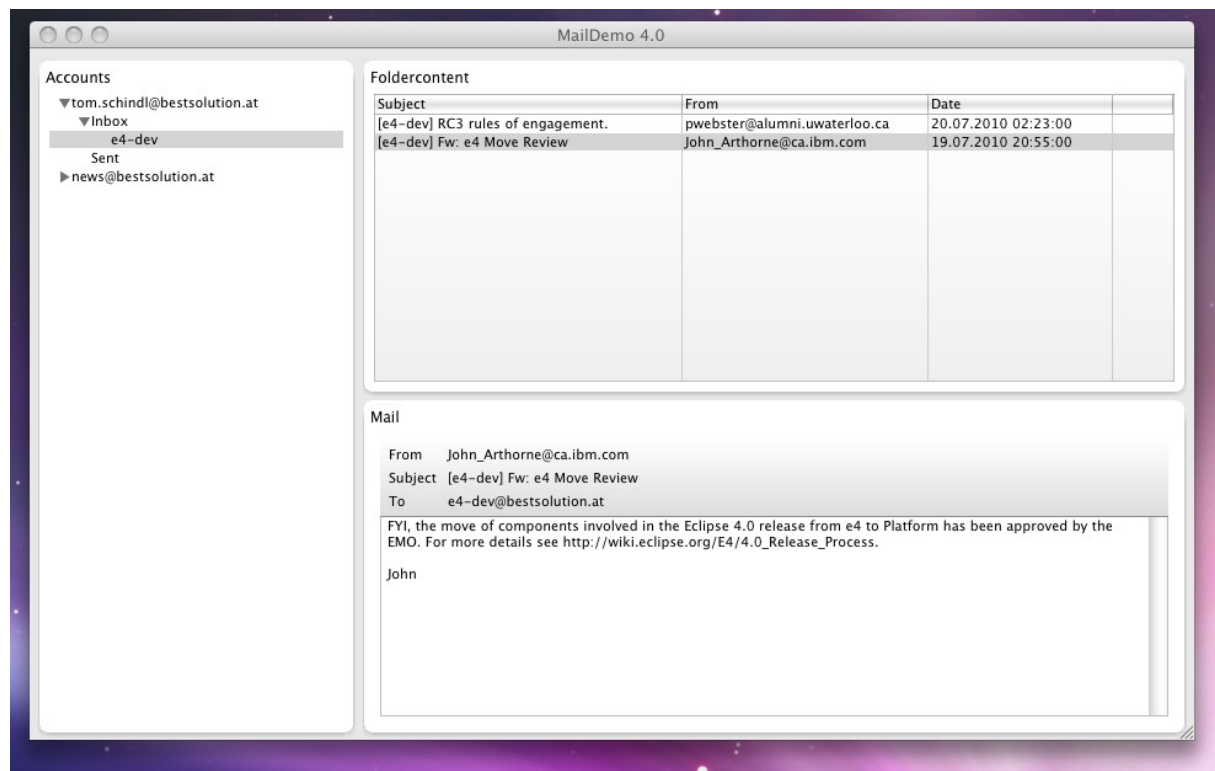

Figure 18: CSS in custom area

The CSS information added to the file are:

```
.maillist {
    background-color: #FFF #EEE 100%;
}

.mailHeader {
    background-color: #FFF #DDD 100%
}
```

But to take effect in our application we need to modify our UI-Code to mark the widget with the CSS-Classnames.

```
public class FolderView {
    @Inject
    public FolderView(Composite parent, @Optional IStylingEngine styleEngine) {
        //Unmodified
        if( styleEngine != null ) {
            styleEngine.setClassname(this.viewer.getControl(), "maillist");
        }
    }
}
```

```
public class MailView {
    @Inject
    public MailView(final Composite composite, @Optional final IStylingEngine styleEngine) {
        //Unmodified
        manager.runAndCollect(new Runnable() {
```

```
public void run() {
    initUI(composite, styleingEngine);
}
});
}

private void initUI(Composite composite, IStylingEngine styleingEngine) {
    //Unmodified
    if( styleingEngine != null ) {
        styleingEngine.setClassname(header, "mailHeader");
    }
}
}
```

There's not much magic, we simply inform the DI-container that we need another service (IStylingEngine) we can use to set a CSS class on the widget.

Want the source code? Look at "Source Zip for Chapter 6" on page 58.

Extended Annotations

To get access to the extended annotations you'll have to add another dependency in your MANIFEST.MF. The name of the dependency is "org.eclipse.e4.core.di.extensions".

@Preference

The next area we are going to take a look at is how to best deal with preferences. A perfect example for preferences are the username, password and host information used to create a MailSession in AccountView.

```
public class AccountView {
    // ...
    private String username = "john";
    private String password = "doe";
    private String host = "tomsondev.bestsolution.com";

    // ...

    public void setUsername(String username) {
        this.username = username;
    }

    public void setPassword(String password) {
        this.password = password;
    }

    public void setHost(String host) {
        this.host = host;
    }
}
```

To get access to values stored in the preferences, the 4.0 Platform provides a special annotation you can use in conjunction with **@Inject** named **@Preference** that can take 2 parameters:

- `nodepath` (optional): the path to the preference node, by default the bundle name is used
- `value`: the value key

```
public class AccountView {  
  
    // ...  
  
    private boolean modified = false;  
  
    // ...  
  
    @Inject  
    public void setUsername(@Preference("username") String username) {  
        this.username = username;  
        this.modified = true;  
    }  
  
    @Inject  
    public void setPassword(@Preference("password") String password) {  
        this.password = password;  
        this.modified = true;  
    }  
  
    @Inject  
    public void setHost(@Preference("host") String host) {  
        this.host = host;  
        this.modified = true;  
    }  
  
    @PostConstruct  
    public void init() {  
        if( username != null && password != null && host != null ) {  
            mailSession = mailSessionFactory.openSession(host, username, password);  
            if( mailSession != null ) {  
                viewer.setInput(mailSession.getAccounts());  
            } else {  
                viewer.setInput(new WritableList());  
            }  
        }  
        modified = false;  
    }  
}
```

After having added this code, the preferences get automagically injected into our view, but we still need to react on the changes and inform the user that he probably wants to recreate the mail session.

A simple solution for now is to remember that values have been modified and the next time the AccountView receives the focus ask the user whether he'd like to reconnect.

@Focus

To inform the framework what method to invoke when the view receives focus, all we need to do is to annotate a method in our code using the **@Focus** which

is coming from "org.eclipse.e4.ui.di" which you should add to your MANIFEST.MF and then add a method like this:

```
@Focus
void onFocus(@Named(IServiceConstants.ACTIVE_SHELL) Shell shell) {
    if( modified ) {
        if( MessageDialog.openQuestion(shell,
            "AccountInfos Modified",
            "The account informations have been modified would you like to reconnect with them?")
        ) {
            init();
            if( mailSession == null ) {
                MessageDialog.openWarning(shell,
                    "Connection failed",
                    "Opening a connecting to the mail server failed.");
            }
        }
    }
}
```

Want the source code? Look at "Source Zip for Chapter 7" on page 58.

Menus and @Execute

In the previous chapter we added preferences support to our AccountView. Now we'll now add a dialog we use to edit those preferences:

- Open the Application.e4xmi
- Select the "Trimmed Window" in the Tree and select the "Main Menu" checkbox:

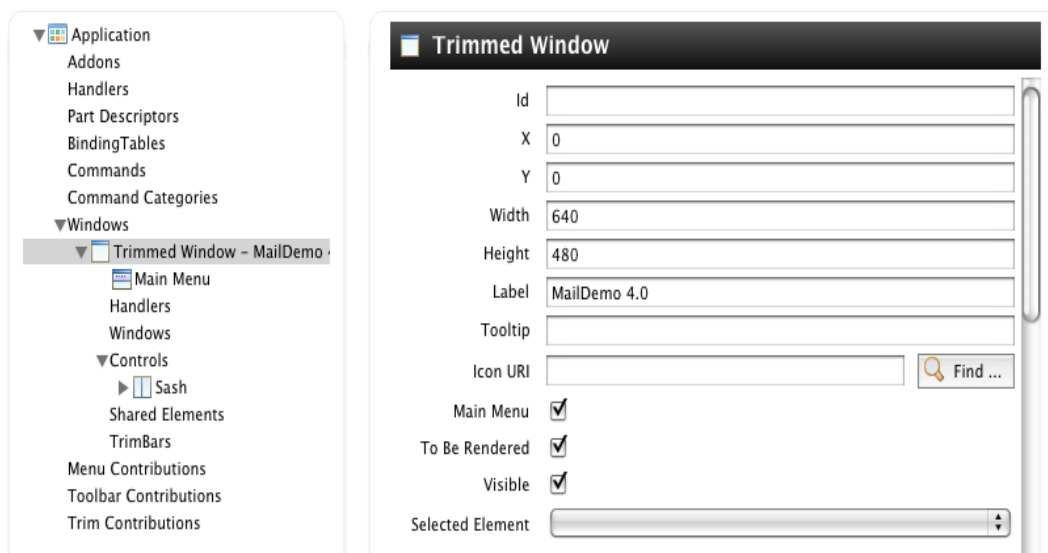

Figure 19: Add main menu

- Create a structure like this

Figure 20: Create the menu structure

d) Click on the Class URI and enter the following information

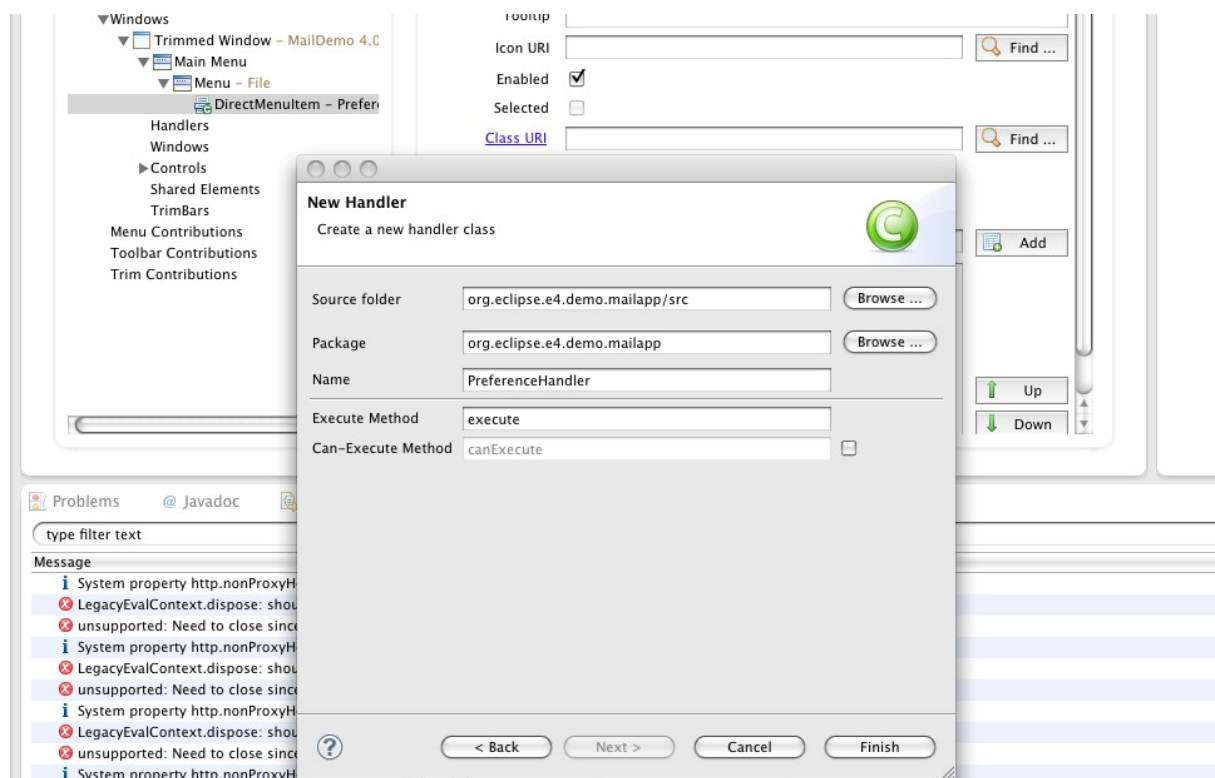

Figure 21: Create handler class

This will generate a class like this:

```
public class PreferenceHandler {
```

```
@Execute
public void execute() {
}
}
```

In the above steps we've connected the MenuItem directly to a Java-Class. Now at the moment the user selects the MenuItem, the framework calls the method annotated with **@Execute**.

Before going on to implement the Dialog and the Handler you need to add the following bundles to your MANIFEST.MF:

- org.eclipse.e4.core.contexts
- org.eclipse.equinox.preferences
- org.eclipse.equinox.common

The implementation of the dialog looks like this:

```
public class PreferenceDialog extends TitleAreaDialog {

    @Inject
    @Preference("username")
    private String username;

    @Inject
    @Preference("password")
    private String password;

    @Inject
    @Preference("host")
    private String host;

    private Text usernameField;
    private Text passwordField;
    private Text hostField;

    @Inject
    public PreferenceDialog(@Named(IServiceConstants.ACTIVE_SHELL) Shell parentShell) {
        super(parentShell);
    }

    @Override
    protected Control createDialogArea(Composite parent) {
        Composite area = (Composite) super.createDialogArea(parent);

        getShell().setText("Connection informations");
        setTitle("Connection informations");
        setMessage("Configure the connection informations");

        Composite container = new Composite(area, SWT.NONE);
        container.setLayoutData(new GridData(GridData.FILL_BOTH));
        container.setLayout(new GridLayout(2, false));

        Label l = new Label(container, SWT.NONE);
        l.setText("Username");

        usernameField = new Text(container, SWT.BORDER);
        usernameField.setText(username == null ? "" : username);
    }
}
```

```

usernameField.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));

l = new Label(container, SWT.NONE);
l.setText("Password");

passwordField = new Text(container, SWT.BORDER);
passwordField.setText(password == null ? "" : password);
passwordField.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));

l = new Label(container, SWT.NONE);
l.setText("Host");

hostField = new Text(container, SWT.BORDER);
hostField.setText(host == null ? "" : host);
hostField.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));

return area;
}

@Override
protected void okPressed() {
    IEclipsePreferences prefs = new InstanceScope().getNode("org.eclipse.e4.demo.mailapp");
    prefs.put("username", usernameField.getText());
    prefs.put("password", passwordField.getText());
    prefs.put("host", hostField.getText());

    try {
        prefs.flush();
        super.okPressed();
    } catch (BackingStoreException e) {
        ErrorDialog.openError(getShell(), "Error",
            "Error while storing preferences",
            new Status(IStatus.ERROR, "org.eclipse.e4.demo.mailapp", e.getMessage(), e)
        );
    }
}
}

```

You will notice that we are using DI here as well in order to get the current preference's value. The useage of DI is not restricted to the framework, instead you can use it in your own code as well to create instances.

The implementation of the PreferenceHandler shows how one uses the DI framework in custom code to create an instance of a class.

```

@Execute
public void execute(IEclipseContext context) {
    PreferenceDialog dialog = ContextInjectionFactory.make(PreferenceDialog.class, context);
    dialog.open();
}

```

Figure 22: Connection Configuration

Want the source code? Look at "Source Zip for Chapter 8" on page 58.

The Event System

Another major change coming with the Eclipse 4.0 Application Platform is the event system provided. The 4.0 Application Platform does not invent its own but uses the EventAdmin-Bus provided by OSGi instead (you are free to substitute through your own implementation just in case you are not happy with the default one!).

The first thing we do is to register ourselves as a listener to the MailSession and **post** an event into the system. Before writing the code you'll have to add some more bundles:

- org.eclipse.e4.core.services
- org.eclipse.osgi.services

```
public class AccountView {

    //Unmodified

    private ISessionListener listener;

    @Inject
    @Optional
    private IEventBroker eventBroker;
```

```

@Inject
public AccountView(Composite parent, IMailSessionFactory mailSessionFactory) {

    //Unmodified
    listener = new ISessionListener() {
        public void mailAdded(IFolder folder, IMail mail) {
            if( eventBroker != null ) {
                Map<String, Object> map = new HashMap<String, Object>();
                map.put(EventConstants.NEW_MAIL_TAG_FOLDER, folder);
                map.put(EventConstants.NEW_MAIL_TAG_MAIL, mail);
                eventBroker.post(EventConstants.NEW_MAIL, map);
            }
        }
    };
}

//Unmodified

@PostConstruct
public void init() {
    if( username != null && password != null && host != null ) {
        if( mailSession != null ) {
            mailSession.removeListener(listener);
        }

        mailSession = mailSessionFactory.openSession(host, username, password);
        if( mailSession != null ) {
            viewer.setInput(mailSession.getAccounts());
            mailSession.addListener(listener);
        } else {
            viewer.setInput(new WritableList());
        }
    }
    modified = false;
}

@PreDestroy
void cleanUp() {
    if( mailSession != null && listener != null ) {
        mailSession.removeListener(listener);
    }
}
}

```

The code is quite straightforward, the only interesting thing is that we are using **"post"** - meaning that we are not blocking until all receivers processed the event. If we want the event to be delivered in a synchronous fashion we would have used **"send"**.

Code parts that want to get informed about those events are subscribing them to the EventBroker like this:

```

public class FolderView {

    //Unmodified

    @Inject
    @Optional
    private IEventBroker eventBroker;
    private EventHandler eventHandler;
}

```

```

private IFolder folder;

//Unmodified

@PostConstruct
void hookEvents() {
    if( eventBroker != null ) {
        eventBroker.subscribe(EventConstants.NEW_MAIL, new EventHandler() {

            public void handleEvent(final Event event) {
                if( event.getProperty(EventConstants.NEW_MAIL_TAG_FOLDER) == folder ) {
                    viewer.getControl().getDisplay().asyncExec(new Runnable() {
                        public void run() {
                            viewer.add(event.getProperty(EventConstants.NEW_MAIL_TAG_MAIL));
                        }
                    });
                }
            }
        });
    }
}

@PreDestroy
void unhookEvents() {
    if( eventBroker != null && eventHandler != null ) {
        eventBroker.unsubscribe(eventHandler);
    }
}

@Inject
public void setFolder(@Named(IServiceConstants.ACTIVE_SELECTION) @Optional IFolder folder) {
    if( folder != null ) {
        this.folder = folder;
        viewer.setInput(folder.getSession().getMails(folder, 0, folder.getMailCount()));
    }
}
}

```

It is important to note that this is the ONLY event system available and all notifications are passed through this system (e.g. creation of widgets like the shells for workbench windows, ...).

Want the source code? Look at "Source Zip for EventSystem" on page 58.

Advanced Eclipse 4.0 - Contributing Fragments

Until now our application is created out of one single "monolithic" bundle and application model definition, but that is not how a typical Eclipse-RCP-Application is made up. One of the strengths of Eclipse 3.x has been that an application could be made up from different bundles who contributed pieces to make up a complete application.

e4 is no different in this aspect but contributing to the model is done a bit differently. What you do is to contribute small fragments to a base application model and then the Eclipse 4.0 Application Platform merges those fragments

into the final model used to create the application.

A first and very important thing when contributing is that the elements in the base model we want to contribute to have to, have an `elementId` (in the editor shown as "Id").

You should open our `Application.e4xmi` and check:

- the `Application-Element` has the Id:
`org.eclipse.e4.demo.mailapp.application`
- the `File-Menu-Element` has the Id:
`org.eclipse.e4.demo.mailapp.filemenu`

The next thing we do is to create new OSGi-bundle named "`org.eclipse.e4.demo.mailapp.newmail`" and add the following dependencies:

- `org.eclipse.e4.core.di`
- `javax.inject`
- `org.eclipse.e4.ui.services`
- `org.eclipse.swt`
- `org.eclipse.e4.demo.mailapp.mailservice`
- `org.eclipse.e4.ui.model.workbench`
- `org.eclipse.e4.ui.workbench`
- `org.eclipse.e4.core.contexts`
- `javax.annotation`
- `org.eclipse.jface`
- `org.eclipse.jface.databinding`
- `org.eclipse.core.databinding`
- `org.eclipse.core.databinding.observable`
- `org.eclipse.core.databinding.property`
- `org.eclipse.core.databinding.beans`

Now we create a Model-Fragment using "File > New > Other ..." and "e4 > Model > New Model Fragment".

We are going to contribute the following things to the base model:

- A Command to the Application-element
- A Handler to the Application-element
- A `HandledMenuItem` to the File-Menu-element

Contributing a Command-Element

The first element we contribute is a Command-Element that is contributed to the Application-Element of our base model.

- In the Fragment-Editor we select the ModelFragments entry and press the "Add ..." -button
- We press the "Find ..." -button next to the "Element Id"-TextField that helps us to find the correct element id of the application-element

Figure 23: Select Application-Element Id

- We press the "Find ..." -button next to the "Featurename"-TextField that helps us to find the feature-name (=attribute-name) the contributed Command should be stored in.

Figure 24: Select Featurename

- d) Select Command in the drop down click the button next to it
 e) Fill the "Element Id" and "Name"-Fields like this:

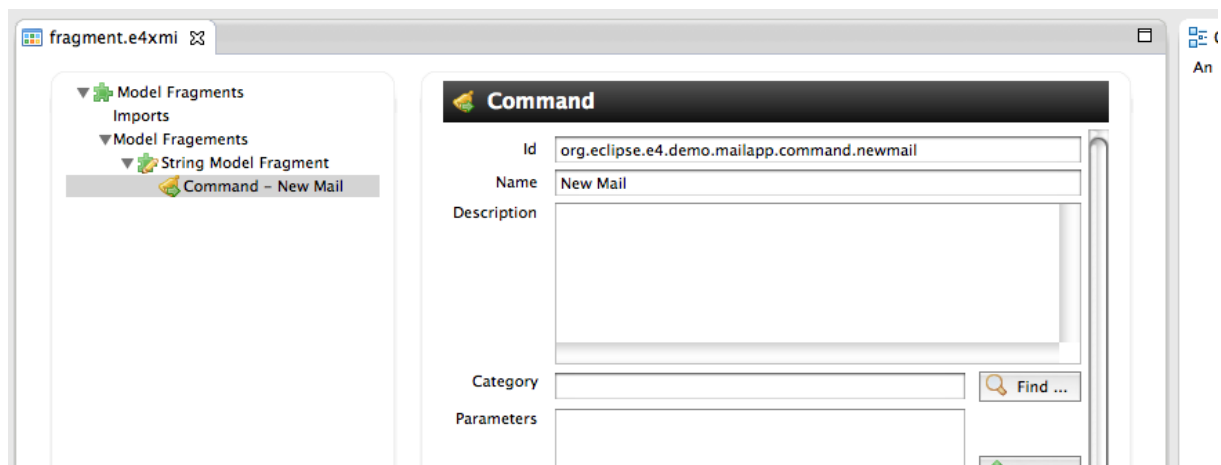

Figure 25: Edit Command Element

Contributing a Handler

The next element we contribute is a Handler that gets connected to our command and will be called when the command is executed.

- a) Add another "String Model Fragment"
- b) Set "Element Id" to "org.eclipse.e4.demo.mailapp.application" and "Featurename" to "handlers"
- c) Add a Handler-Element
- d) Press the "Find..."-button next to the Command text field

Figure 26: Connect to command

- e) Press the "Class URI"-Link and enter the following information

Figure 27: Set a handler class

Contributing a HandledMenuItem

The next thing we contribute is MenuItem to the File-Menu that is connected to our command.

- Add another "String Model Fragment"
- Set "Element Id" to "org.eclipse.e4.demo.mailapp.filemenu", "Featurename" to "children" and "Position in list" to "first"
- Add an HandledMenuItem-Element
- Set the "Label"-Attribute to "New Mail"
- Press the "Find ..." -button next to the "Command"-TextField

Figure 28: Connect MenuItem to Command

Contributing a ToolItem

Open the Application.e4xmi and add

- a TrimBar with side-value set to Top
- a ToolBar with Id set to "org.eclipse.e4.demo.mailapp.maintoolbar"

The model should now look like this:

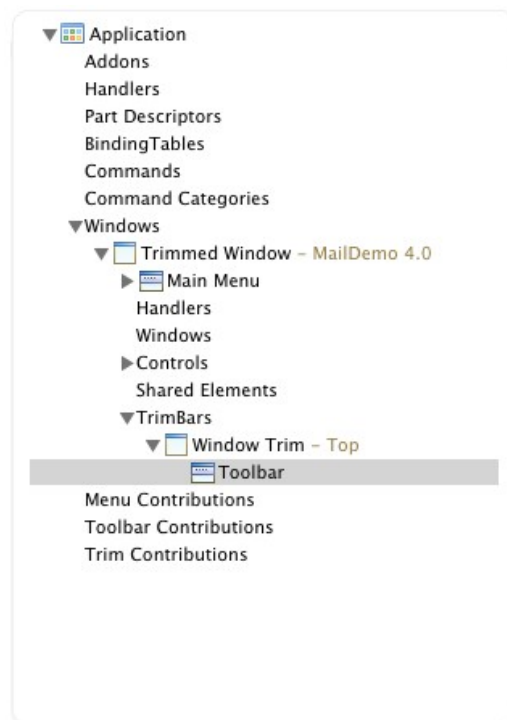

Figure 29: Toolbar Addition

Open the default.css-File and add the following entry:

```
.MTrimBar {
    background-color: #CFCFCF #A8A8A8 100%;
}
```

Back in our fragment.e4xmi, execute the following steps:

- Add another "String Model Fragment"
- Set "Element Id" to "org.eclipse.e4.demo.mailapp.maintoolbar" and "Featurename" to "children"
- Add a HandledToolItem, set its label to "New Mail" and connect it also to the "org.eclipse.e4.demo.mailapp.command.newmail"-command

We have to add 2 more elements:

- Command-Element and the following properties:
 - Id: org.eclipse.e4.demo.mailapp.command.sendmail
 - Name: "Send Mail"
- Handler:
 - connected to org.eclipse.e4.demo.mailapp.command.sendmail-command

- Class-URI: pointing to a class named SendMail

Figure 30: Final Fragment

Dynamic UI creation

That's it for the model. Let's now work on the Java code of the handler.

```
public class NewMailHandler {

    @Execute
    public void execute(final MApplication application, IMailSession mailSession) {
        // Create the window
        final MTrimmedWindow window = MBasicFactory.INSTANCE.createTrimmedWindow();
        window.getTags().add("temporaryObject");
        window.setHeight(500);
        window.setWidth(600);

        // Create the toolbar
        MTrimBar topTrim = MBasicFactory.INSTANCE.createTrimBar();
        topTrim.setSide(SideValue.TOP);
        window.getTrimBars().add(topTrim);

        MToolBar toolbar = MMenuFactory.INSTANCE.createToolBar();
        topTrim.getChildren().add(toolbar);

        MHandledToolItem sendItem = MMenuFactory.INSTANCE.createHandledToolItem();
        sendItem.setLabel("Send");
        sendItem.setIconURI("platform:/plugin/org.eclipse.e4.demo.mailapp.newmail/images/email_go.png");
    }

    for( MCommand cmd : application.getCommands() ) {
        if( "org.eclipse.e4.demo.mailapp.command.sendmail".equals(cmd.getElementId()) ) {
            sendItem.setCommand(cmd);
        }
    }

    toolbar.getChildren().add(sendItem);

    // Create the mail editor
}
```

```

MPart part = MBasicFactory.INSTANCE.createPart();
part.setContributionURI(
    "platform:/plugin/org.eclipse.e4.demo.mailapp.newmail/org.eclipse.e4.demo.mailapp.newmail.EditMailView");
window.getChildren().add(part);
application.getChildren().add(window);
window.getContext().set(IMail.class, mailSession.createMail());
}

@CanExecute
public boolean canExecute(@Optional IMailSession mailSession) {
    return mailSession != null;
}
}

```

What we are doing here is to interface with the application model to add a new window that has a toolbar at the top and a part to edit a mail that will take up the rest of the window's area.

I think what you see above is one of the coolest things in the Eclipse 4.0 Application Platform. You have access to the application model and are allowed to modify it at runtime, adding, removing, moving things around.

We also introduced a new **@CanExecute**-annotation that can be used on Command-Handlers to compute the enabled state. The framework calls this method whenever the values defined in the parameters of the method change, in our case the new command is only enabled if there's a `IMailSession` available.

Before we can run the application we need to make some changes to our existing code:

```

public class AccountView {
    // Unmodified code

    @Inject
    @Optional
    private MApplication application;

    @Inject
    public AccountView(Composite parent, IMailSessionFactory mailSessionFactory) {
        // Unmodified code

        // Work around for 4.0 Bug of not cleaning up on Window-close
        viewer.getControl().addDisposeListener(new DisposeListener() {
            public void widgetDisposed(DisposeEvent e) {
                cleanUp();
            }
        });
    }

    // Unmodified code

    @PostConstruct
    public void init() {
        // Unmodified code

        if( application != null ) {
            application.getContext().set(IMailSession.class, mailSession);
        }
    }
}

```

```

    }
}

// Unmodified code

@Focus
void onFocus(@Named(IServiceConstants.ACTIVE_SHELL) Shell shell) {
    // Unmodified code

    if( application != null ) {
        application.getContext().set(IMailSession.class, mailSession);
    }
}
}

```

So here we access to the MApplication-Element to get easy access to the context attached to it and store the current mail-session there.

You may notice that I also introduced a work-around for a bug in the 4.0-code base that deals with **@PreDestroy** when a window is closed. This bug hasn't been a problem so far for our tutorial, because we only had a single window but as of now is going to affect us.

We also have to fix the problem in the FolderView:

```

public class FolderView {
    // Unmodified code

    @Inject
    public FolderView(Composite parent, @Optional IStylingEngine styleEngine) {
        // Unmodified code

        // Work around for 4.0 Bug of not cleaning up on Window-close
        viewer.getControl().addDisposeListener(new DisposeListener() {
            public void widgetDisposed(DisposeEvent e) {
                unhookEvents();
            }
        });
    }
}

```

The last 2 things missing are now:

a) The implementation of our EditMailView:

```

public class EditMailView {
    @Inject
    private MTrimmedWindow window;

    private ComboViewer viewer;

    private IObservableValue master = new WritableValue();

    private ObservablesManager manager = new ObservablesManager();

    @Inject
    public EditMailView(final Composite container) {
        manager.runAndCollect(new Runnable() {
            public void run() {
                createUI(container);
            }
        });
    }
}

```

```

    });
}

private void createUI(Composite container) {
    Composite parent = new Composite(container, SWT.NONE);
    parent.setLayout(new GridLayout(2, false));

    Label l = new Label(parent, SWT.NONE);
    l.setText("Account");

    viewer = new ComboViewer(parent);
    viewer.getControl().setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
    viewer.setLabelProvider(new LabelProvider() {
        @Override
        public String getText(Object element) {
            return ((IAccount)element).getName();
        }
    });
    viewer.addSelectionChangedListener(new ISelectionChangedListener() {
        public void selectionChanged(SelectionChangedEvent event) {
            window.getContext().set(IAccount.class,
                (IAccount)((IStructuredSelection)event.getSelection()).getFirstElement());
        }
    });
    viewer.setContentProvider(new ObservableListContentProvider());

    DataBindingContext dbc = new DataBindingContext();
    IWidgetValueProperty prop = WidgetProperties.text(SWT.Modify);

    l = new Label(parent, SWT.NONE);
    l.setText("To");

    Text t = new Text(parent, SWT.BORDER);
    t.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
    dbc.bindValue(prop.observe(t), BeanProperties.value("to").observeDetail(master));

    l = new Label(parent, SWT.NONE);
    l.setText("Subject");

    t = new Text(parent, SWT.BORDER);
    t.setLayoutData(new GridData(GridData.FILL_HORIZONTAL));
    dbc.bindValue(prop.observe(t), BeanProperties.value("subject").observeDetail(master));

    BeanProperties.value("subject").observeDetail(master).addValueChangeListener(
        new IValueChangeListener() {
            public void handleValueChange(ValueChangeEvent event) {
                String value = (String) event.diff.getNewValue();
                value = value == null ? "" : value;

                if( window != null ) {
                    window.setLabel("New Mail: " + value);
                }
            }
        }
    );

    t = new Text(parent, SWT.BORDER|SWT.MULTI|SWT.WRAP);
    GridData gd = new GridData(GridData.FILL_BOTH);
    gd.horizontalSpan = 2;
    t.setLayoutData(gd);
    dbc.bindValue(prop.observe(t), BeanProperties.value("body").observeDetail(master));
}

```

```

@PreDestroy
void cleanUp() {
    manager.dispose();
}

@Inject
void setMailSession(IMailSession session) {
    if( session != null ) {
        viewer.setInput(session.getAccounts());
    } else {
        if( ! viewer.getControl().isDisposed() ) {
            viewer.setInput(new WritableList());
        }
    }
}

@Inject
@Optional
void setMail(IMail mail) {
    master.setValue(mail);
}
}

```

Not really a lot of magic besides that we are here pushing the ComboViewers-Account selection into the TrimmedWindow's context.

When we introduced DI, I said you can think of the IEclipseContext used for injection as a Map of type Map<String, Object> but the IEclipseContext is not a flat but an hierarchical structure. There is an application-context (attached to the Application-Element), a window-context (attached to a Window-Element), a Part-Context attached to a Part,

b) The implementation of the SendMail handler:

```

public class SendMail {
    @Execute
    public void sendMail(@Named(IServiceConstants.ACTIVE_SHELL) Shell shell,
        MTrimmedWindow window, IMail mail, IAccount account, IPresentationEngine engine) {

        if( mail.getTo() == null || mail.getTo().trim().length() == 0 ||
            mail.getTo().indexOf('@') == -1 ) {

            MessageDialog.openError(shell, "No Recipient", "Your mail has no recipient.");
            return;
        }

        if( mail.getSubject() == null || mail.getSubject().trim().length() == 0 ) {
            if( ! MessageDialog.openQuestion(shell, "No subject",
                "You have not set a subject would you like to proceed?") ) {
                return;
            }
        }

        account.getSession().sendMail(account, mail);

        // Bug in 4.0 we need to tear down through the presentation-engine
        engine.removeGui(window);
        window.getParent().getChildren().remove(window);
    }
}

```

```

}

@CanExecute
public boolean canExecute(@Optional IAccount account, @Optional IMail mail) {
    return account != null && mail != null;
}
}

```

The only interesting thing is the use of the `IPresentationEngine` that we need to use because of another problem with removing already existing workbench-windows from the application in the 4.0 codebase.

Because we have to use the `IPresentationEngine`, we should briefly explain what it is and what it does. The `IPresentationEngine` is the one who translates the Application-Model into an UI and reflects all modifications you make on the model (like the one we made in `NewMailHandler`) in the UI - ranging from easy ones like updating the label to such complex ones like adding new windows, moving views and much more.

We can now run our application which looks like this:

Figure 31: Final Application

You'll immediately notice a problem after having started and stopped the application once. The new mail windows we created are restored on restart so we need to take care on shutdown to remove them before the workbench state is persisted.

The only available solution in 4.0 is to install a lifecycle-handler in the product definition in "org.eclipse.e4.demo.mailapp".

Create a class named LifecycleHandler which looks like this:

```
public class LifecycleHandler {
    @PreSave
    void cleanupModel(MApplication application, EModelService modelService) {
        List<Object> list = modelService.findElements(application, null, null,
            Collections.singletonList("temporaryObject"));

        for (Object o : list) {
            EcoreUtil.delete((EObject) o, true);
        }
    }
}
```

There are 4 annotations available to plug into the lifecycle:

- **@PostContextCreate:** Called after the application context is created
- **@ProcessAdditions:** Called before the model is passed to the renderer
- **@ProcessRemovals:** Called before the model is passed to the renderer
- **@PreSave:** Called before the model is persisted

The other nice thing is that the Eclipse 4.0 Application Platform provides us a services to interface with the application model and we are using it here to remove objects tagged with "temporaryObject", yet still we need some EMF help to clean the elements (note this is the first and only time in this tutorial that you see that the application model is defined using EMF)

Finally we need to register the lifecycle handler in our product definition that now looks like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<?eclipse version="3.4"?>
<plugin>
  <extension
    id="product"
    point="org.eclipse.core.runtime.products">
    <product
      application="org.eclipse.e4.ui.workbench.swt.E4Application"
      name="Mail App">
      <property
        name="appName"
        value="Mail App">
      </property>
      <property
        name="applicationXMI"
        value="org.eclipse.e4.demo.mailapp/Application.e4xmi">
      </property>
      <property
        name="applicationCSS"
        value="platform:/plugin/org.eclipse.e4.demo.mailapp/css/default.css">
      </property>
    </property>
  </product>
</extension>
</plugin>
```

```
        name="lifeCycleURI"
        value="platform:/plugin/org.eclipse.e4.demo.mailapp/org.eclipse.e4.demo.mailapp.Life
cycleHandler">
    </property>
</product>
</extension>

</plugin>
```

Improve Usability with Keybindings

A professional application allows the user to use the application using the keyboard as well and so, we add as a "final polish" keybindings.

We can only define keybindings for actions triggered through commands (so we can't add one for our Connection Configuration dialog which is launched using a `DirectMenuItem`).

The first thing we need to create are binding contexts that define under which circumstance a keybinding is active.

- a) Open the `Application.e4xmi` and check the "Root Context" checkbox
- b) We set the "Id" to `"org.eclipse.e4.demo.mailapp.app.context"` and the Name "In the Application"
- c) Create a child context with "Id" set to `"org.eclipse.e4.demo.mailapp.mainwindow.context"` and the Name to "In Main Window".
- d) Bug workaround: There's a small bug in the Binding-Implementation which yields an exception if no `"org.eclipse.ui.contexts.dialog"` is available. So we add a dummy context with this id.

Now we have to define two `BindingTables` that we connect to the contexts defined before.

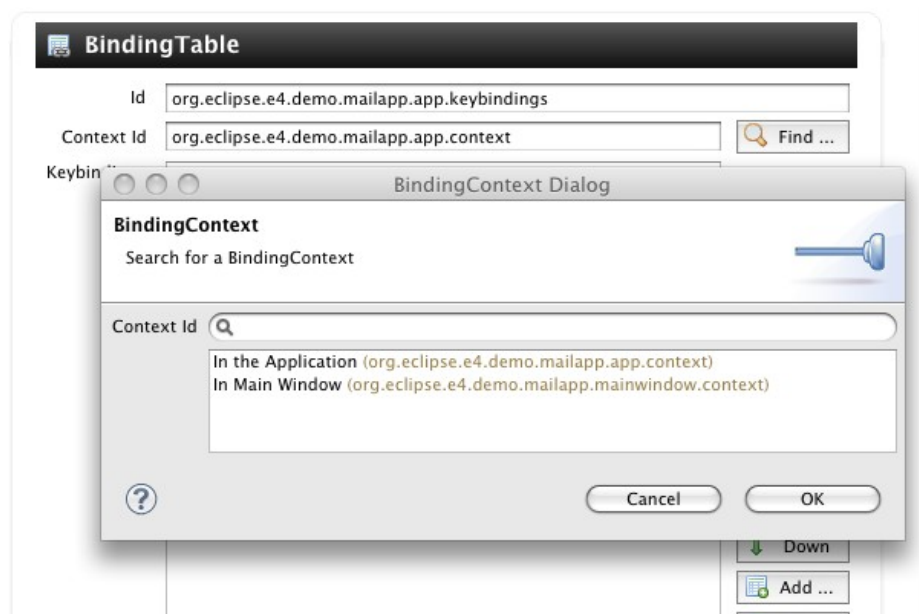

Figure 32: Connect BindingTable to Contexts

- BindingTable 1:
 - Id: org.eclipse.e4.demo.mailapp.app.keybindings
 - Context Id: org.eclipse.e4.demo.mailapp.app.context
- BindingTable 2:
 - Id: org.eclipse.e4.demo.mailapp.mainwindow.keybindings
 - Context Id: org.eclipse.e4.demo.mailapp.mainwindow.context

Now we are ready to create keybindings. The first one we create is a special one to shutdown the application (CTRL+Q/CMD+Q).

You should create the following Model-Elements:

- A Command:
 - Id: org.eclipse.e4.demo.mailapp.command.exit
 - Name: Exit Application
- A Handler:
 - Command: org.eclipse.e4.demo.mailapp.command.exit
 - Class URI pointing to: org.eclipse.e4.demo.mailapp.ExitHandler
- A Separator to the File-Menu
- A HandledMenuItem to the File-Menu with
 - Id: org.eclipse.ui.file.exit (this is important for OS-X users because using this id ensures that the menu entry is moved to the

Application-Menu)

- Label: Exit
- Command: org.eclipse.e4.demo.mailapp.command.exit

The application model looks like this after you have executed the actions above:

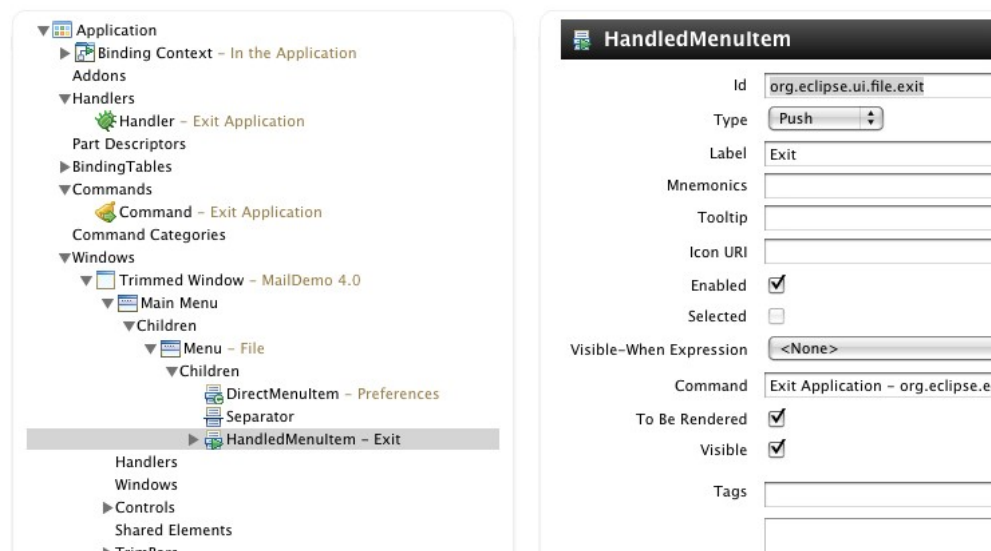

Figure 33: Model Structure

The next model change is to add the KeyBinding to the "org.eclipse.e4.demo.mailapp.app.keybindings"-BindingTable. You'll have to set the following values on the element:

- Sequence: M1+Q
- Command: org.eclipse.e4.demo.mailapp.command.exit

Last step in our model is to

- associate our Application-Element with the "org.eclipse.e4.demo.mailapp.app.context"-Context.
- associate our TrimmedWindow with the "org.eclipse.e4.demo.mailapp.mainwindow.context"-Context

Open the elements and enter the above ids into the "Binding Context"-Field and press "Add".

Finally we implement the ExitHandler class:

```
public class ExitHandler {
    @Execute
    public void execute(@Named(IServiceConstants.ACTIVE_SHELL) Shell shell,
        IPresentationEngine engine) {

        if( MessageDialog.openQuestion(shell, "Exit Application?",
```

```

        "Do you really want to exit the application?") ) {

    engine.stop();

    }
}
}

```

You can now launch your application and hit CTRL/CMD+Q and should be prompted with dialog like this:

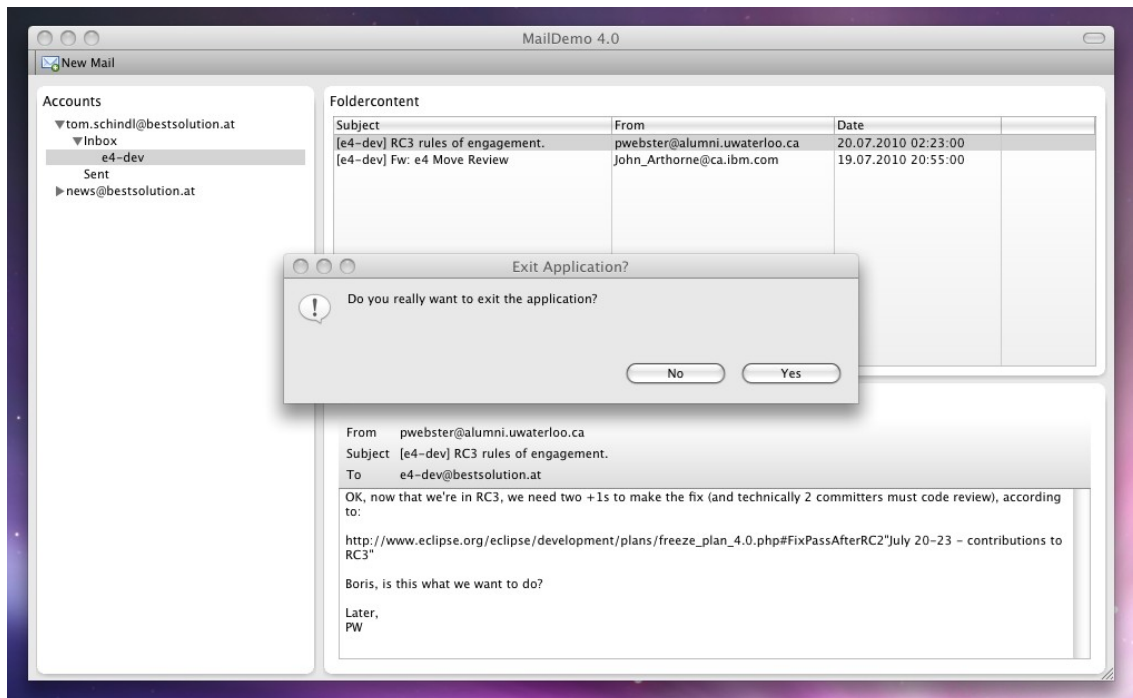

Figure 34: Exit Application Dialog

Last step in the binding story is to contribute a Keybinding for the "New Mail"-Command.

Open the `fragment.e4xmi` and add a new "String Model Fragment" with the following attributes:

- Element Id: `org.eclipse.e4.demo.mailapp.mainwindow.keybindings`
- Featurename: `bindings`

Add a KeyBinding-Element to the elements list and set the following values:

- Sequence: `M1+N`
- Command: `org.eclipse.e4.demo.mailapp.command.newmail`

Closing words

I hope this RCP-Application tutorial has helped introduce you to the most important concepts behind the new Eclipse 4.0 Application Platform and provide you a jump start on writing applications using the Eclipse 4.0 Application Platform.

There is more of course, as we have actually only scratched the surface of this new platform. Here are some topics we haven't yet looked into:

- Customization of the Workbench-Rendering by writing our own Renderers
- Writing our own IPresentationEngine to e.g. use a different Widget-Toolkit like Swing to render the Workbench-UI
- Extending the Workbench Model to introduce your own concepts

- CSS-Themes
- Advanced model contribution using Java-Code

I'd like to remind you once more that the 4.0 release of the SDK is marked as an "Early Adopter Release" and not meant for daily use as your IDE.

The e4-runtime is a new application framework you can use to write UI-Applications. Similar to the 4.0 SDK, you must know that you are running on a bleeding edge platform which has not yet released a stable API nor is bug free.

Still we think if you're starting of with a new RCP-Application you should consider using the Eclipse 4.0 Application Platform but it depends on a case by case base if this makes sense for your project.

All API provided currently by the Eclipse 4.0 Application Platform is provisional and can change in the 4.1 timeframe, so if you decide to use the Eclipse 4.0 Application Platform as your application framework, you should subscribe to the e4-dev-mailing list.

The provisional state of the API should not solely regarded as a disadvantage as you have the opportunity to influence its direction as an early adopter.

We need your *constructive* feedback to make the Eclipse 4.0 Application Platform the most powerful UI-Application-Framework
